

ShipTrip

Peer-to-peer parcel delivery for travellers and senders in Algeria.

May 2026

The app

ShipTrip puts two kinds of people in the same place: travellers who have spare room in their luggage on an upcoming trip, and senders who need a parcel carried along that same route. The sender posts what they need carried, the traveller posts the trip, and the two are matched. They agree on a price, the sender pays into a held wallet, and the money only reaches the traveller after the recipient confirms delivery with a short code.

Cheaper than a courier for the sender, a small income for the traveller, and the platform keeps the money in the middle until everyone is satisfied.

Architecture

The mobile app reaches everything through a single gateway that handles HTTPS and routes each request to the right backend. Two backends sit behind it: a core service that owns accounts, money and the database, and a set of live services that handle long-lived things - chat, notifications, identity uploads and media. The two backends do not call each other directly; they share information through the database and a realtime bus, which means either can be restarted or scaled up without disturbing the other.

The mobile app

Built for iOS and Android, talking to a real backend. A few of the screens, captured from the live build:

Find travelers

Find a traveller.

Done

- Accounts, sign-up and sign-in, with role selection (sender, traveller, or both).
- Trips: a traveller can publish a route with airports, dates and capacity.
- Parcels: a sender can describe a parcel or a product to be bought and delivered.
- Matching: trips and parcels find each other; offers are exchanged and accepted.
- Payments into a held wallet, with frozen pricing on each accepted offer.
- Handover codes: short numeric codes for pickup and delivery, hashed and rate-limited.
- Wallet release: the traveller is paid only when the delivery code is verified.
- Refunds that reverse the held amount cleanly.
- Mobile flows for all of the above, on iOS and Android.
- Notifications between the parties over a live connection.
- Identity submission on the mobile side.

Missing

Chat. Sender and traveller can already coordinate by phone, but in-app chat is on the way.

Identity verification end-to-end. The mobile capture and upload are done; the link between the upload service and the core record is the remaining piece.

Admin dashboard. A back-office surface for moderation, identity review and general oversight.

Stripe. A sandbox payment provider is in place today behind a single switch. Stripe slots into the same place.

Secure channel between backends. The two backend layers authenticate with a shared token in development; production will use mutual certificates.

Worth pointing out

Money is held, not paid. When a sender pays, the amount enters a wallet held against that specific deal. The traveller only receives it after the delivery code is verified. The same hold is reversed cleanly on a refund; the system cannot double-credit.

Private data stays private. Personal details and identity documents live in their own storage, encrypted at rest, and only the strict minimum ever comes back to the device. Identity images go straight to private storage; nothing transits a public URL.

Codes that age out quickly. The six-digit pickup and delivery codes are never stored in readable form. Five wrong attempts lock the code and a new one is issued.

Room to grow. The long-lived parts of the system - chat, notifications, identity uploads - run on a separate layer from the part that handles money, and can be scaled up on their own when traffic grows.
